

What Did We Learn from Deploying Low-Cost Particle Monitors in 20 Homes?

Yizhi Zhang, Tianyuan Li, Raheleh Givehchi, Jeffrey Siegel

Department of Civil and Mineral Engineering, University of Toronto, Canada

Background

- Exposure to particulate matter (PM) has detrimental effects on our health
- Using HVAC filters is one approach to reduce exposure in residences

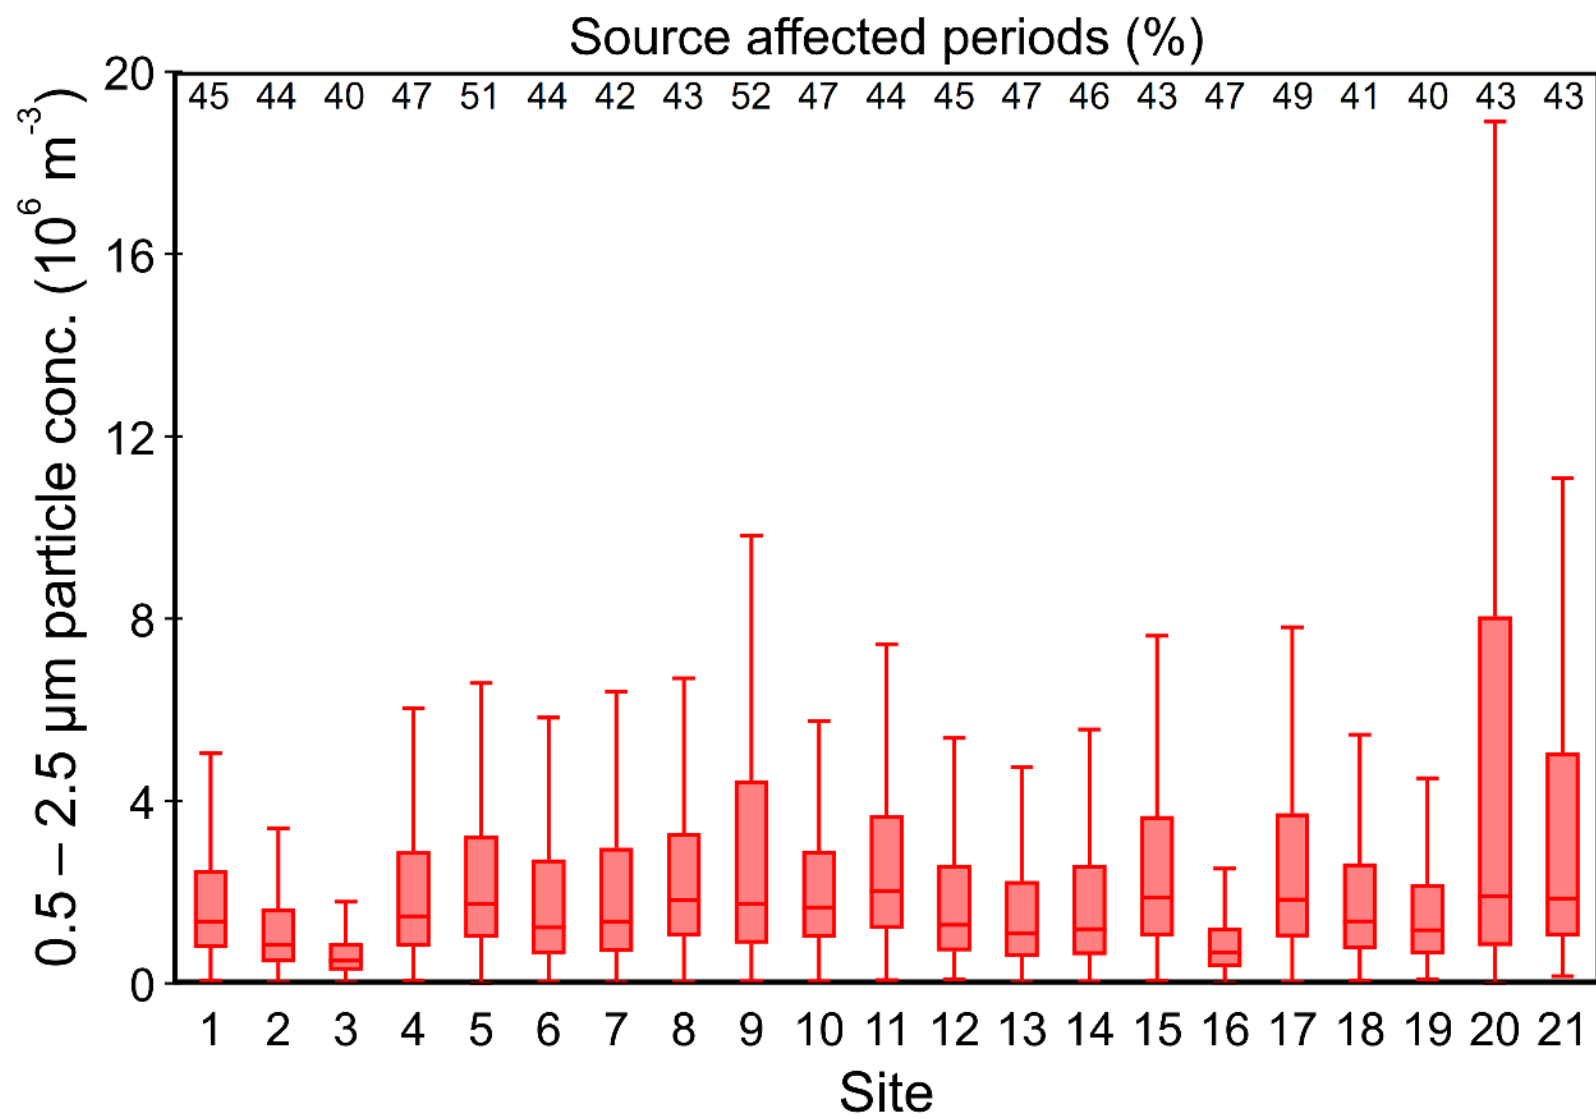

Concentration measurements

- Year-long monitoring in 21 Toronto homes
- Four levels of high-efficiency filters installed, each for 3 months (MERV 8, MERV 8E, MERV 11E, and MERV 14E)
 - MERV = Minimum Efficiency Reporting Value from ASHRAE Standard 52.2
- Collection of HVAC parameters including system operation status
- Low-cost monitor measured $PM_{>0.5 \mu m}$ & $PM_{>2.5 \mu m}$ **every hour**

Long-term filter effectiveness

$$H = 1 - \frac{C_{MERV \#}}{C_{MERV 8}}$$

where: $C_{MERV \#}$ = median concentration of particles when one of MERV 8E, 11E, and 14E filters was installed in the system
 $C_{MERV 8}$ = median concentration of particles when MERV 8 filter was installed in the system

What is going on?

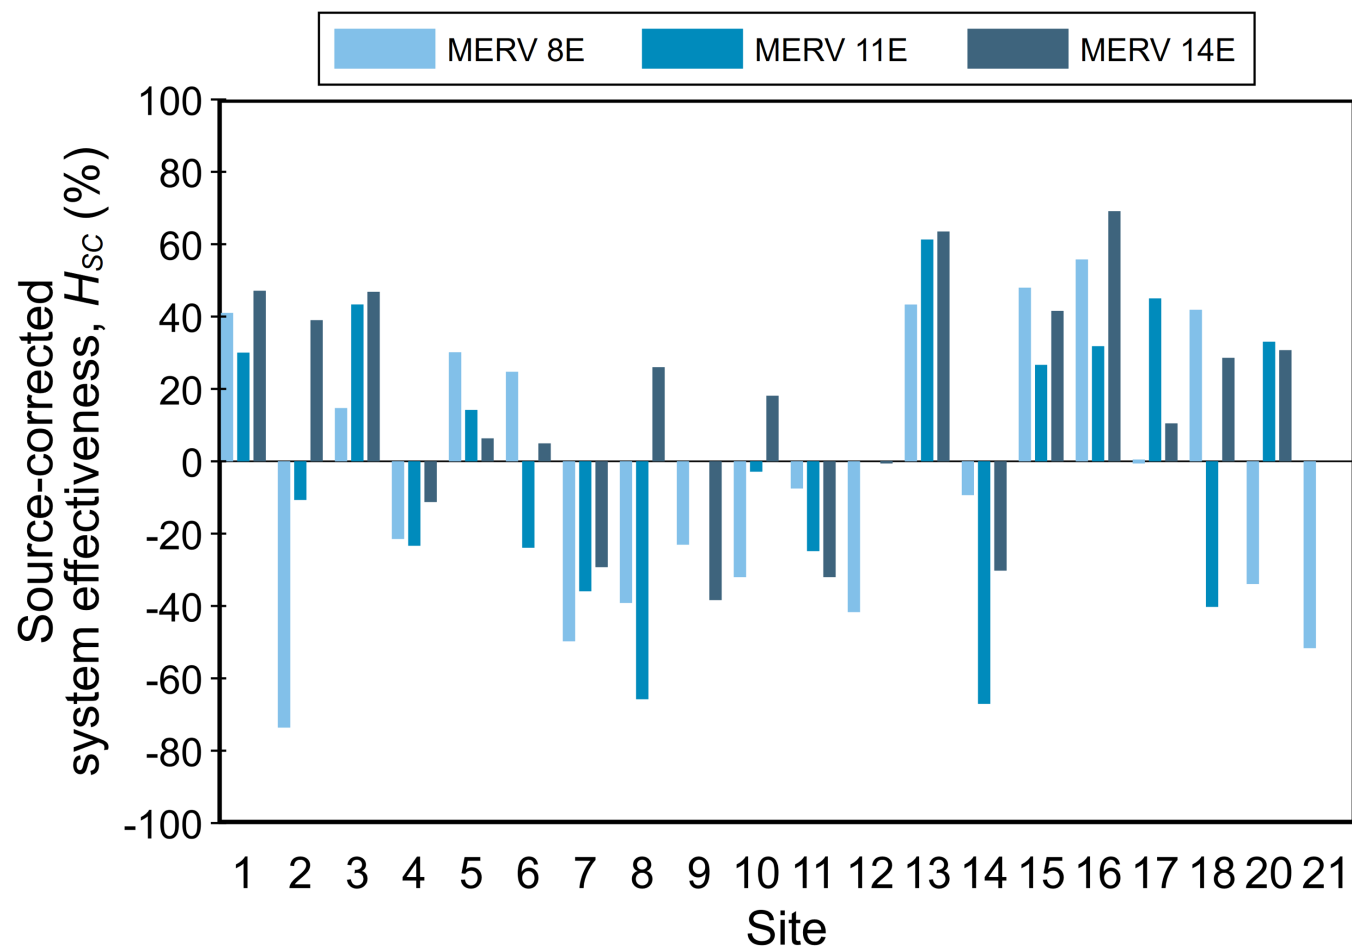

- Runtimes were short (~10% average)
 - Mild weather year, heating-dominated climate
- Buildings were leaky
 - Largely older homes (mostly semi-attached)
 - Filtration couldn't compete with ventilation
- Source pattern becomes important
 - Sources may have been different for different filters

Source-Corrected Long-term filter effectiveness

$$H = 1 - \frac{C_{MERV \#}}{C_{MERV 8}}$$

ONLY when sources
were not active (50-
60% of all data)

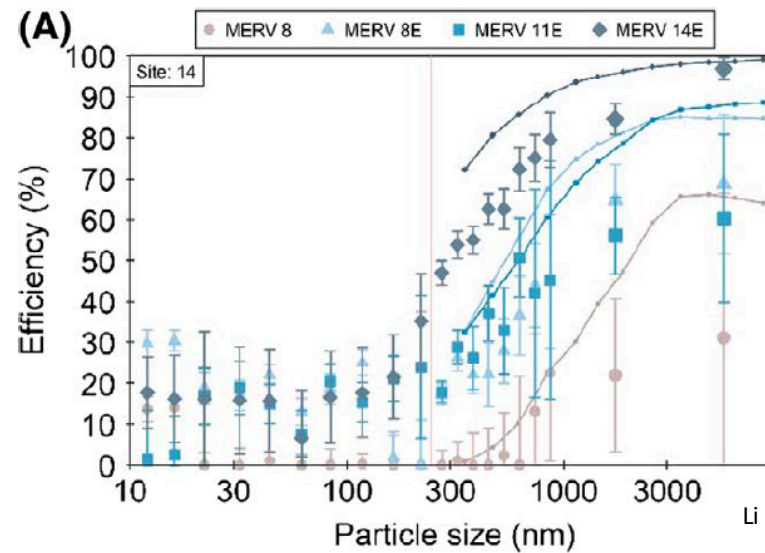

where: $C_{MERV \#}$ = median concentration of particles when one of MERV 8E, 11E, and 14E filters was installed in the system
 $C_{MERV 8}$ = median concentration of particles when MERV 8 filter was installed in the system

Confounding factors

- Lower in-situ efficiency than nominal efficiency
- Low HVAC system runtime

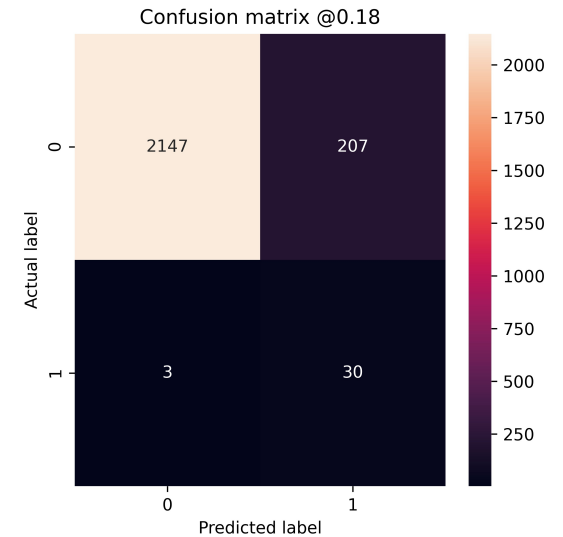

Li and Siegel (2020), *Indoor Air*.

Touchie and Siegel (2018), *Indoor Air*.

Where can we go next?

- Machine learning – are there factors that would allow us to predict indoor concentrations?
 - Short answer – no, not in this data
 - Longer answer – unsupervised model can find elevated concentrations, but can't always predict them (accuracy 47-95%)

Conclusion

- High-efficiency filters have highly variable relative effectiveness
- No conclusive evidence that filters can substantially reduce indoor PM concentration in this sample of homes
- Machine learning (ML) from datasets like these might offer opportunities for control of air cleaning approaches
 - Substantial effort on interpretation and models
 - High time resolution data may be better for ML models
